This is a RAG PDF, this will explain the complete process of creating a RAG application using LangChain.

RAG is a Retrieval-Augmented Generation approach that combines traditional information retrieval techniques with generative models to provide more accurate and contextually relevant responses.

This approach allows the system to leverage both the vast knowledge encoded in the generative model and the specific, up-to-date information retrieved from external sources, resulting in more reliable and context-aware outputs.

In this PDF, we will walk through the steps of setting up a RAG application, including document loading, text splitting, vector store creation, and query handling using LangChain.

By the end of this PDF, readers should have a clear understanding of how to implement a RAG system using LangChain and be able to apply these concepts to their own projects.
